MRI-guided frameless neuronavigation system
for TMS and integrated EEG-TMS

<http://www.emsmedical.net> - sales@emsmedical.net

Introduction

- ✓ The SofTaxic neuronavigation system is a tool used in conjunction with a Magnetic stimulator by researchers in order to guide the direction of the stimulating coil over an area of interest.
- ✓ The system works with the majority of focal stimulating coils available on the market.

Introduction

- ✓ It's based on an optical digitizer that tracks in realtime the position in space of several tools
- ✓ It can be used with 2 different models of digitizer: Polaris Vicra and polaris Spectra from NDI
- ✓ The main difference between the two is the acquisition volume and the frame rate

Why Neuronavigation ?

It gives you information about your stimulation's cortical target with high accuracy (2-3 mm) in real time.

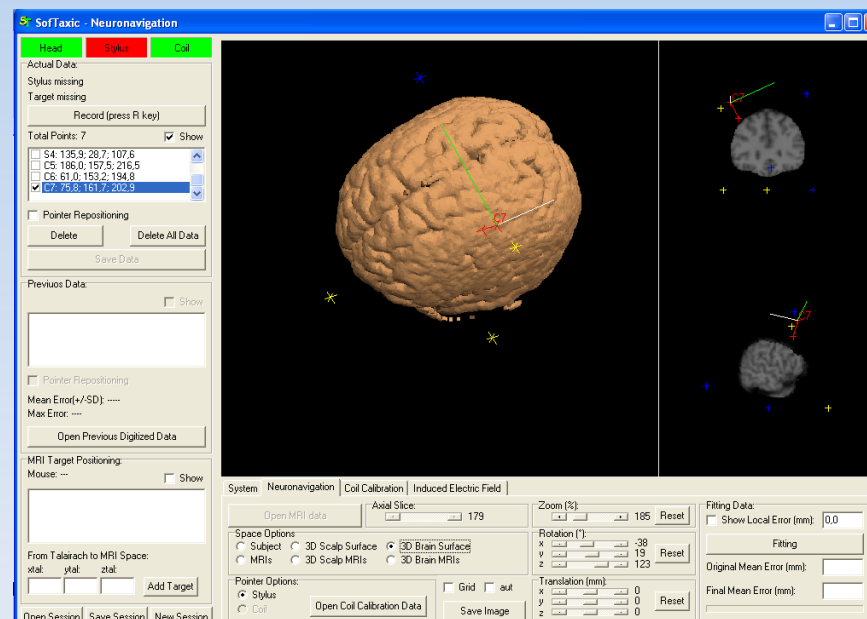

By using a navigation system users can achieve better accuracy and repeatability for their experiments

MRI-guided coil positioning

- The SofTactic system is able to guide accurately the TMS coil positioning, by using MRIs
- The TMS stimulation brain site can be localized on to the 2D MRIs and on to the 3D realistic MR-constructed brain model
- Furthermore, spatial coordinates of the stimulated sites are referred to the PAN*, stereotaxic Talairach and MRIs coordinate systems

Localization

Localization is by far the most important feature that every navigation system implements, it allows:

- ✓ Easiness of target's search thanks to the visual feedback
- ✓ Repositioning to a previous target with high accuracy

Is that important ?

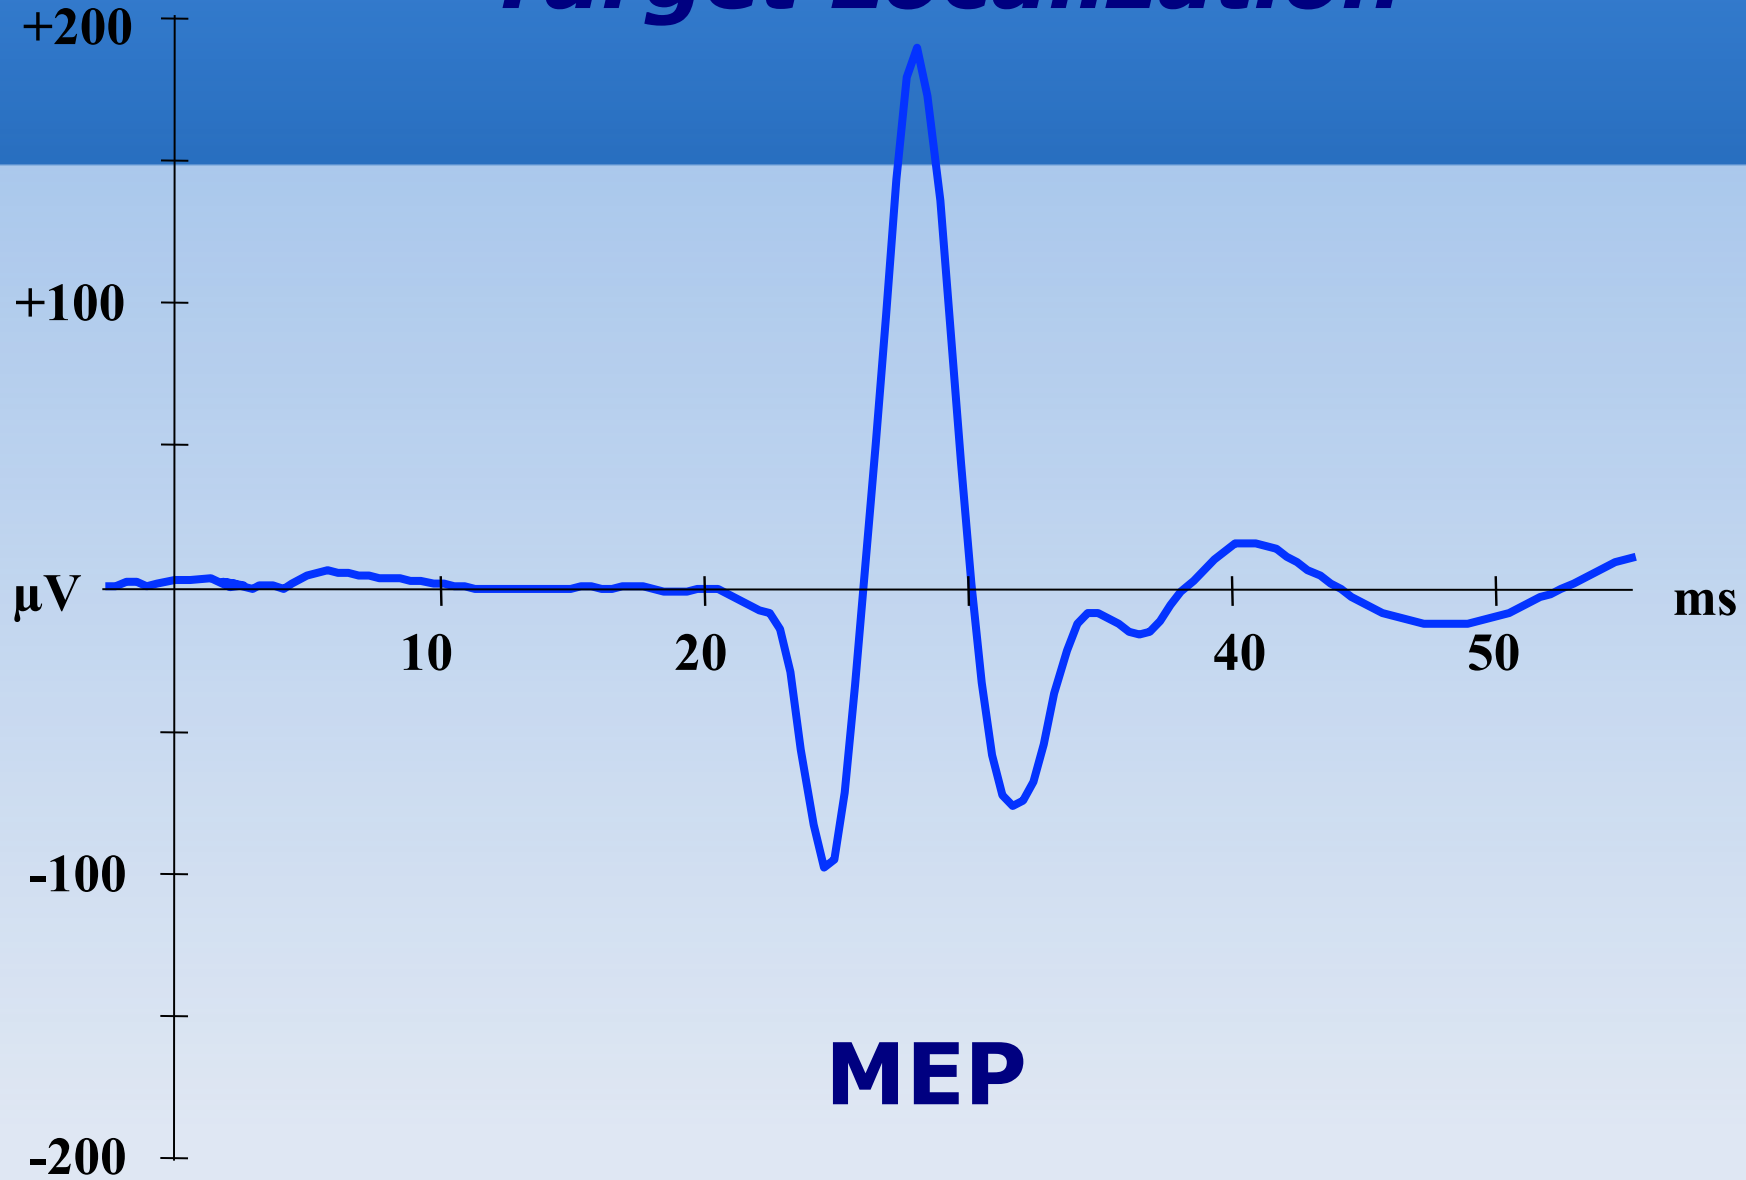

- ✓ Why bother using a navigation system ? It's yet another tool you have to learn !
- ✓ How do users use TMS without a Neuronavigation system ?
- ✓ Alternatives ?

Motor Cortex

Target Localization

Other areas ?

Target localization

Problem: what if we need to hit an area other than the motor cortex / spine ?

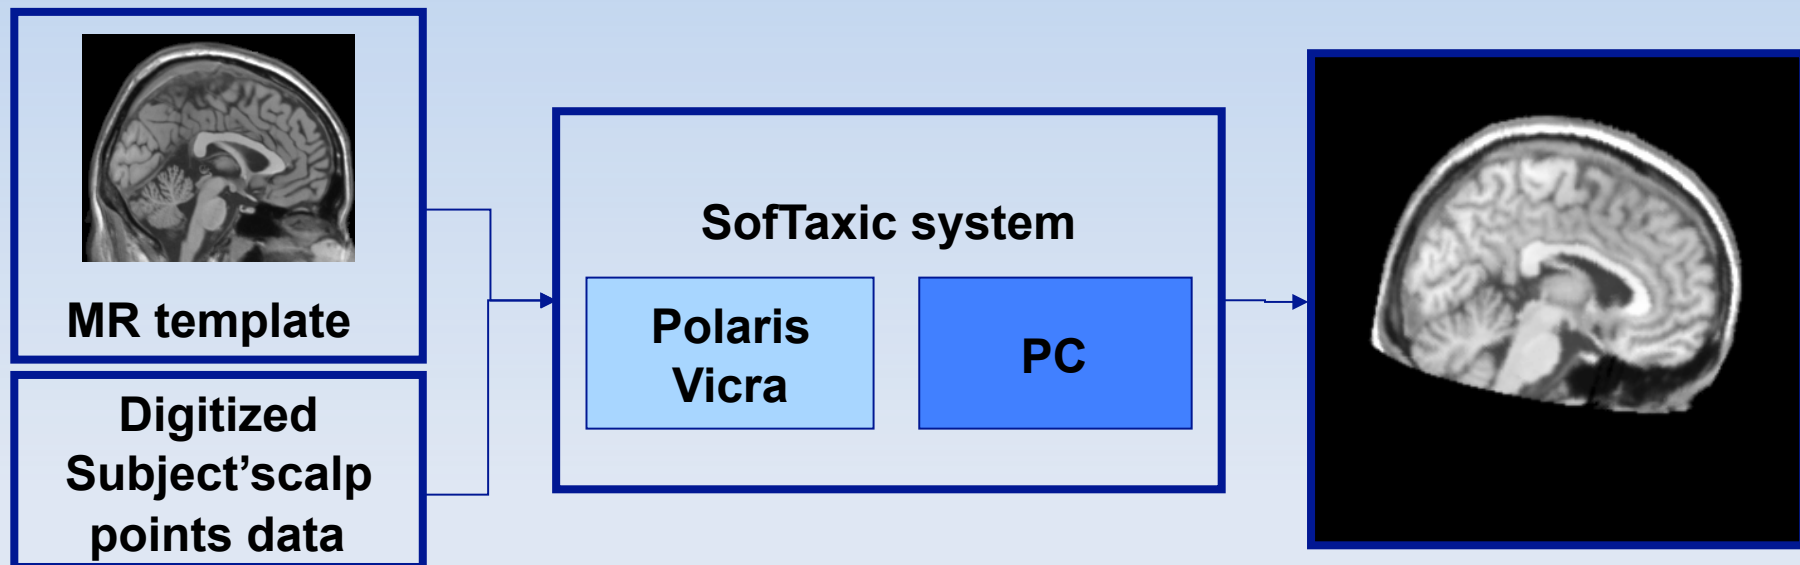

What if my subject's no MRI ?

- ✓ We provide a solution for the problem: it's called MRIs estimation.
- ✓ This feature makes the system appealing to researches (e.g. psychologist) that have no access to an MRI scanner, but they still want to investigate brain functionality by means of TMS.
- ✓ Nobody else can do the same, not with our level of accuracy.

MRIs Estimation

- ✓ If the subject does not have his MRIs, the TMS stimulation can be guided by using an estimated set of MRIs
- ✓ The estimated set of MRIs is calculated using an innovative and accurate 3D warping procedure, able to preserve anatomical scalp-brain correlates of an MR template.
- ✓ The 3D warping procedure works on a set of points, digitized from the subject's scalp by mean of a computer-assisted procedure.

MRIs Estimation

- ✓ The accuracy of the estimation procedure was evaluated on 28 healthy adults (mean age 35 ys) having own MRIs used as gold standard
- ✓ In this evaluation, the TMS stimulation brain site was localized using both own and estimated MRIs, while the position of the TMS coil was kept fixed onto the subject's scalp overhanging one of the 64 S.I.10-10 sites

Own MRIs

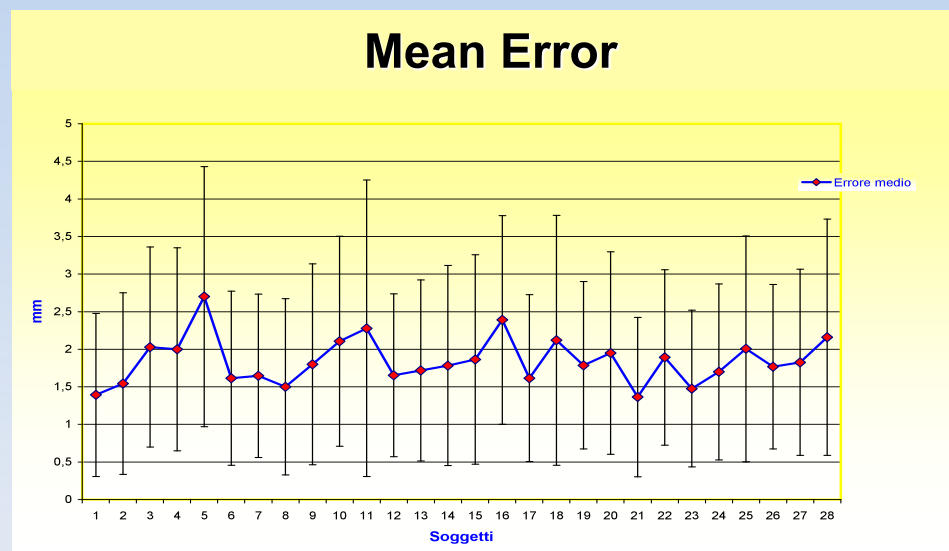

Estimated MRIs

MRIs Estimation

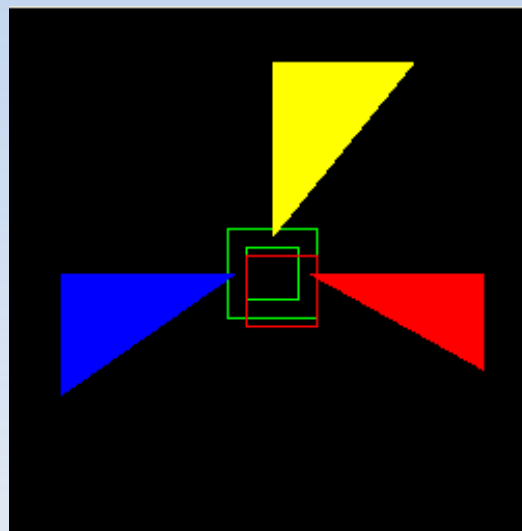

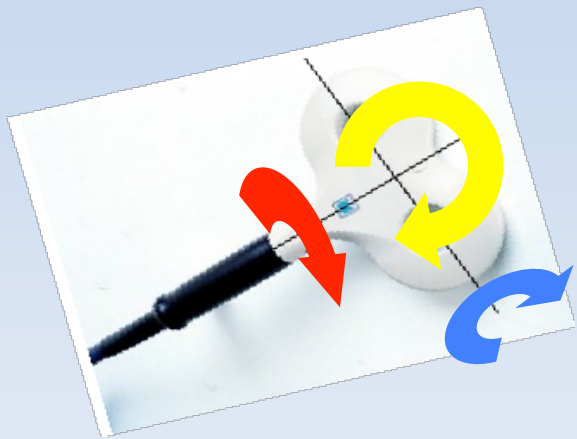

- ✓ In order to evaluate the accuracy of the estimated MRIs respect to the own images, for each one of these 64 scalp sites we calculated the difference (Euclidean distance - Talairach space) between the stimulation brain site localized used the own and the estimated MRIs, respectively
- ✓ The results indicate a mean error of 1,84 mm, with a maximum error of 4,32 mm, lower than TMS spatial resolution

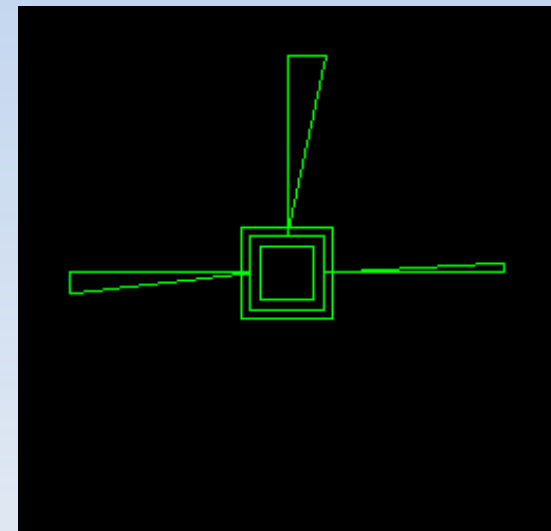

COIL repositioning and stability

- **Stability:** it is a tool that enable us to quantify the coil shifts from the stimulation target during the experiment
- **Repositioning:** we are able to hit again the very same target on the subject, even during different sessions.
- **Fundamental for studies that needs to check pre/post conditions (e.g. farmaceutical studies)**
- **Up to 2 coils can be tracked simultaneously.**

Bad overlapping

Good overlapping

TMS Induced Electrical field

- ✓ In order to fully characterized a TMS brain stimulation, it is very important not only to know the stimulated area, but also the magnitude and the effective direction of the TMS induced E-field over the brain tissue
- ✓ This induced E-field depends on many factors, like stimulator settings, geometry and orientation of the TMS coil, local brain geometry, brain electrical conductivity
- ✓ The SofTaxic system calculates on-line the TMS induced electrical field onto the 3D realistic MR-constructed brain model of the subject by means of the BEM mathematic method (Boundary Element Method)

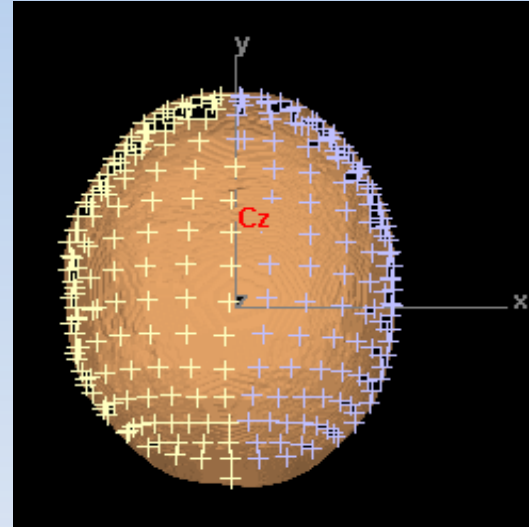

Assisted electrodes placement

- ✓ SofTactic is able to calculate the locations of 249 scalp electrode sites of the Standard International 10-5 system (S.I.10-5) onto a virtual reconstruction of the subject's scalp
- ✓ These locations can be used to assist EEG electrode placement onto the subject's scalp by using digitizer facility

Electrode sites of the S.I.10-5

MRI subject head registration

- ✓ In the MRI-guided TMS neuronavigation, the main potential source of low accuracy takes place during the registration procedure, which is made in order to co-register the subject's head and his MRIs in a common coordinate system
- ✓ This procedure uses two analogous set of craniometrical landmarks (i.e. left and right preauricular points and nasion) digitized from the subject and localized onto his MRIs, respectively
- ✓ The SofTaxis system uses an automatic best-fit surface procedure, to define the best MRI-subject's head registration

EEG - TMS

- ✓ The most advanced TMS applications involves the use of combined EEG-TMS recordings.
- ✓ We provide to users the tools they need for today's and tomorrow's applications needs.
- ✓ By using the SofTaxic system + BrainAmp amplifiers we can enable the simultaneous recording of EEG + Coil positions.

EEG - TMS

The ability to synchronize the stimulation with EEG data acquisition allows us to do combined data recording EEG-TMS and MEPs-TMS:

Marker type: Marker Description:

Acquired point: P1TrCS
Tool used: Coil 1

Coil movements

The open architecture of Analyzer 2 gives us the ability to

perform additional inspections and analysis to our data:

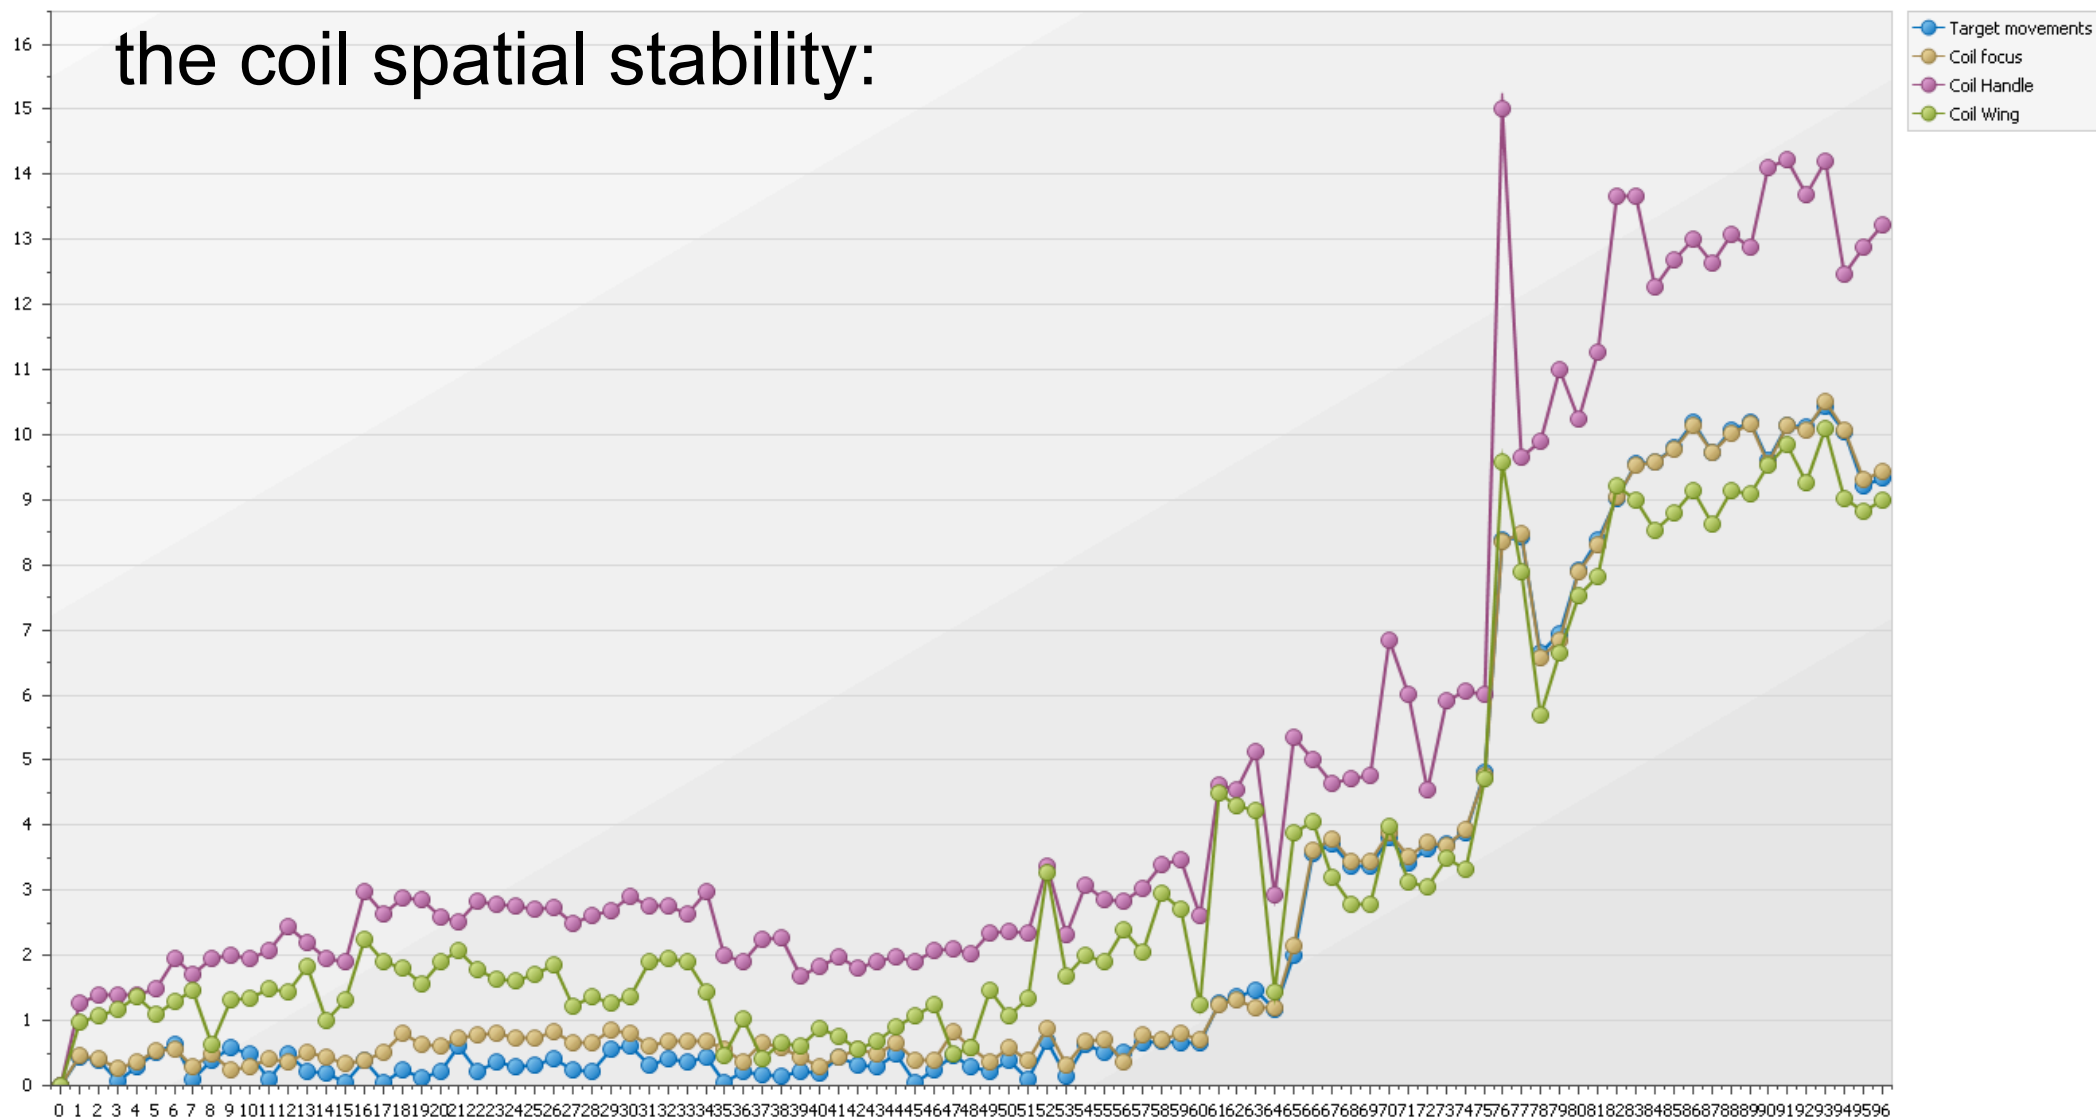

Coil movements

We can do a rejection of artifacts using criteria based on

the coil spatial stability:

EEG Maps and MEPs

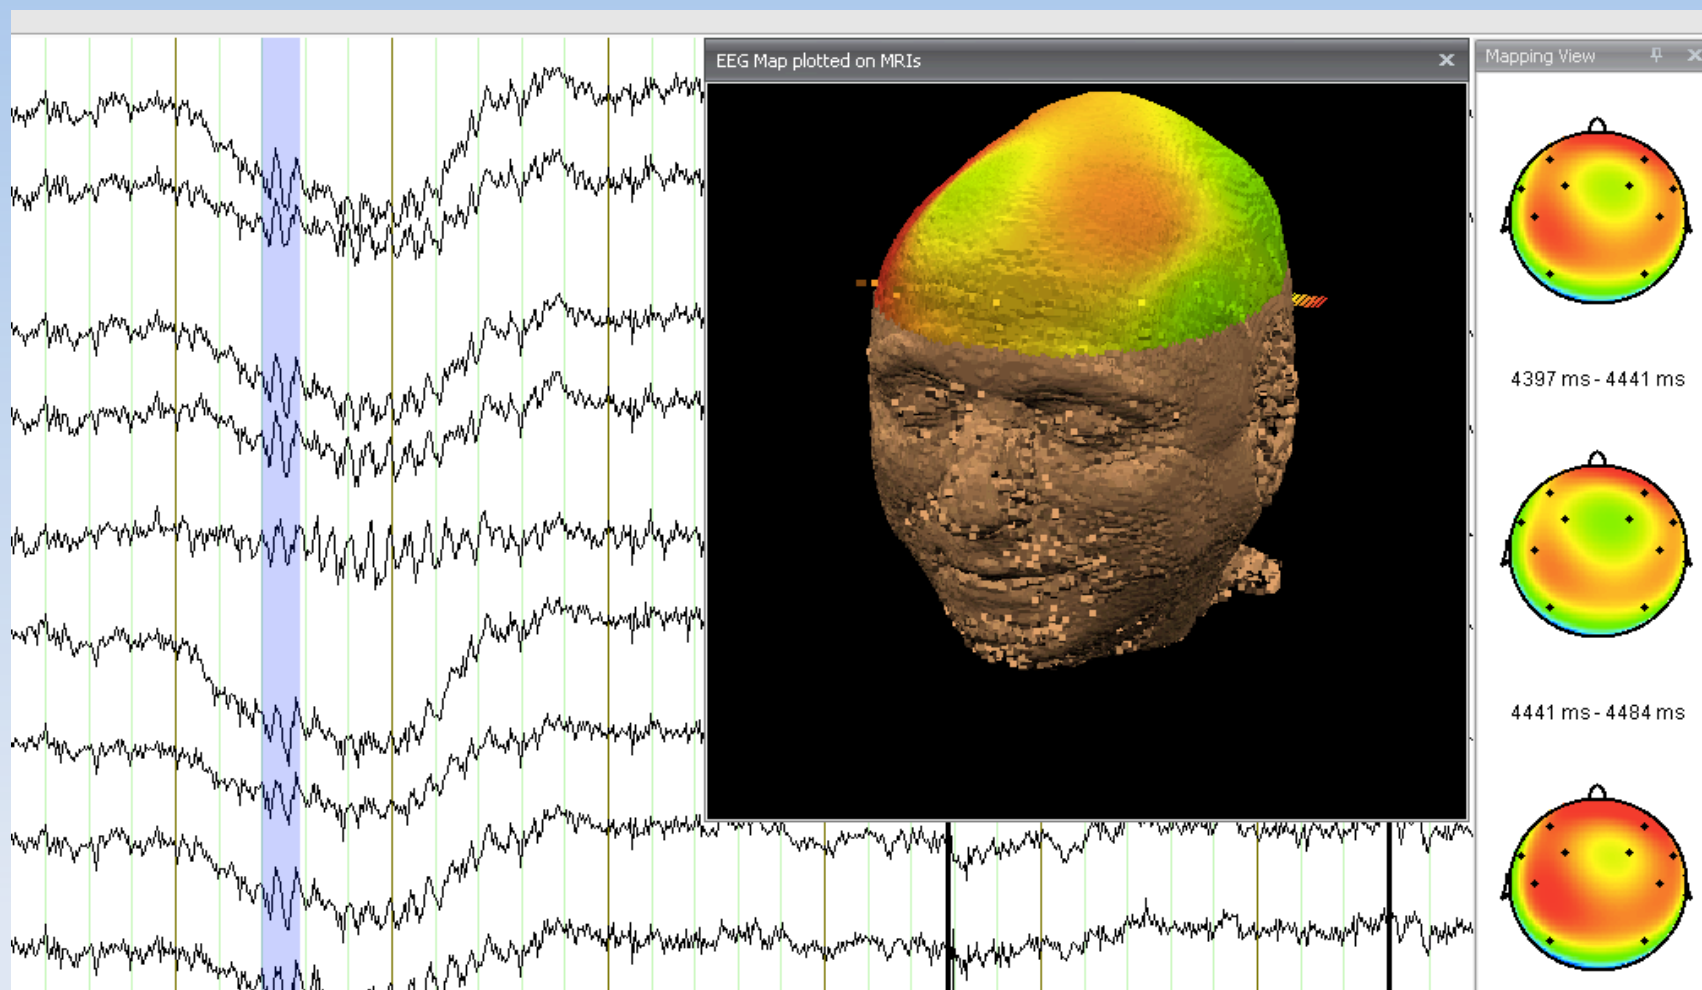

We can send the information about the EEG data back to the neuronavigation system, using its visualization tools:

EEG Maps and MEPs

Here we can see an example of a EEG MAP plotted on 3D reconstruction of a real subject's head inside Analyzer 2.0

EEG Maps and MEPs

MEPs maps are built by using the amplitude values of motor responses to TMS stimuli, each different stimulation site evokes a different amplitude of the motor response thus it's plotted with a different color:

Highlights:

- ✓ Optical digitizer: 2 models from NDI are supported
- ✓ Tight integration with Analyzer 2
- ✓ Doesn't need subject's MRIs for TMS: high accuracy
MRIs estimation
- ✓ MR Volume export with target points
- ✓ Automatic coil calibration
- ✓ 2 Coils tracking
